# cannTEEN: an observational, longitudinal study investigating how cannabis differentially affects teenagers and adults

**Dr Will Lawn**

**SSA annual conference**

**Friday 8<sup>th</sup> November 2019**

**Clinical Psychopharmacology Unit**

**University College London**

will.lawn@ucl.ac.uk

@Will\_Lawn

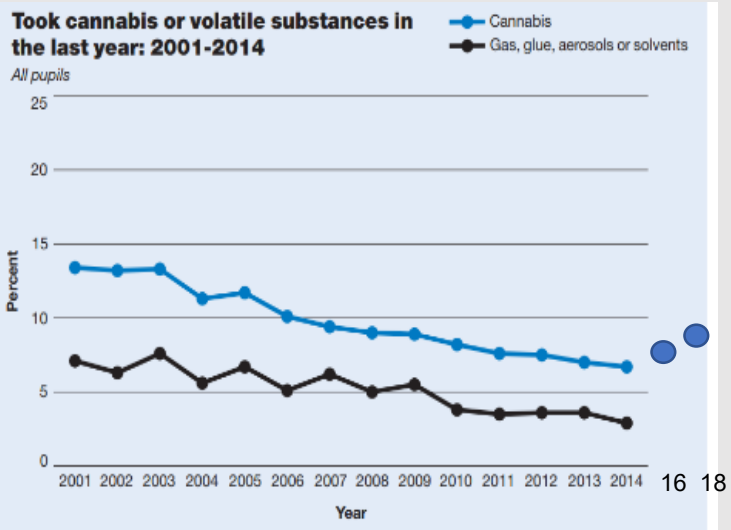

No conflicts of interest

- Introduction: adolescence as a period of heightened vulnerability to the harmful effects of cannabis?
- Methods and aims of the CannTeen study
- Preliminary cross-sectional results
  - Addiction
  - Psychotic-like symptoms
  - Neural correlates of reward processing
- Discussion

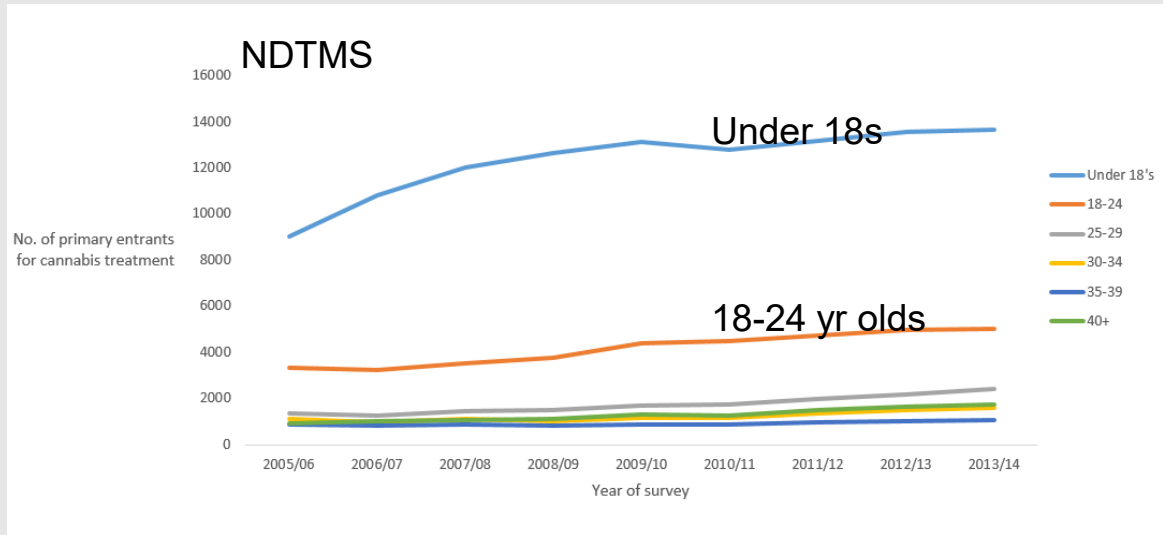

- Introduction: adolescence as a period of heightened vulnerability to the harmful effects of cannabis?
- Methods and aims of the CannTeen study
- Preliminary cross-sectional results
  - Addiction
  - Depression
  - Psychotic-like symptoms
  - Neural correlates of reward processing
- Discussion

# Teenage cannabis use

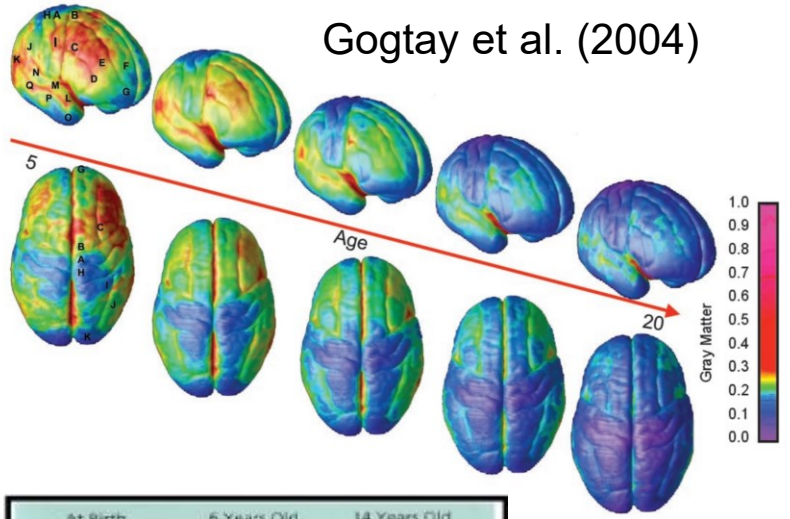

- 19.3% of 15 year olds in England used cannabis in the last year (NHS Digital).
- Downward trend in England since 2000, but creeping back up since 2014?

Treatment need for cannabis problems is greatest for teenagers

**11-15 year olds.** Smoking, drinking and drug use among young people in England, NHS Digital

- Neural, cognitive, emotional and social development continues.
- Endocannabinoid system continues to develop.
- Reward processing and executive functions still maturing.

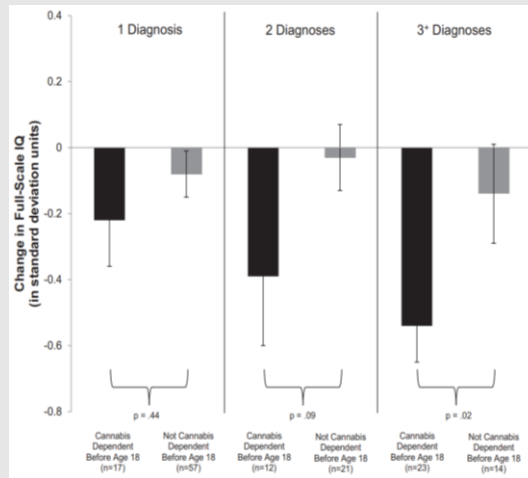

***A time of heightened vulnerability?***

# Greater vulnerability to cannabis during adolescence?

- IQ and cognition.
- Psychosis.
- Brain structure & function.
- Addiction.

Meier et al. (2012)

Survival of no dependence

Ehlers et al. (2010)

- Lack of direct comparisons between current teenage and adult cannabis users, or inclusion of age-matched controls.
- Often cross-sectional designs with retrospective measures of age-of-onset.
- Lack of research into changes *during* teenage years, relative to *during* adult years.
- Crude measures of cannabis use and lacking measures of biological cannabinoid levels.
- No study has compared longitudinal changes in teenage cannabis users with adult cannabis users (who did *not* use regularly as a teenager), against age-matched controls.

- **Methods and aims of the CannTeen study**
- Preliminary cross-sectional results
  - Addiction
  - Psychotic-like symptoms
  - Neural correlates of reward processing
- Discussion

- Aim: to investigate the differential associations between cannabis use and mental health, cognition and brain health in teenagers and adults.
- General hypothesis: over one year, teenage cannabis users (relative to age-matched controls) will show a worse trajectory than adult cannabis users (relative to age-matched controls) in the above domains.

Abstinent from alcohol and cannabis for 12 hours, all other drugs for 24 hours.

### Study 1: Longitudinal (n=272)

Baseline	+3 months	+6 months	+9 months	+12 months
$\beta \lambda *$	$\lambda *$	$\lambda *$	$\lambda *$	$\lambda *$

### Study 2: Longitudinal s/fMRI

(n=140)

Cannabis user groups: =teenage =adult,

Control groups: =teenage =adult

### Study 1

- Observational, longitudinal.
- Four groups.
- n=68 in each. Sex split evenly.
- Once every 3 months, for 1 year.

### Study 2

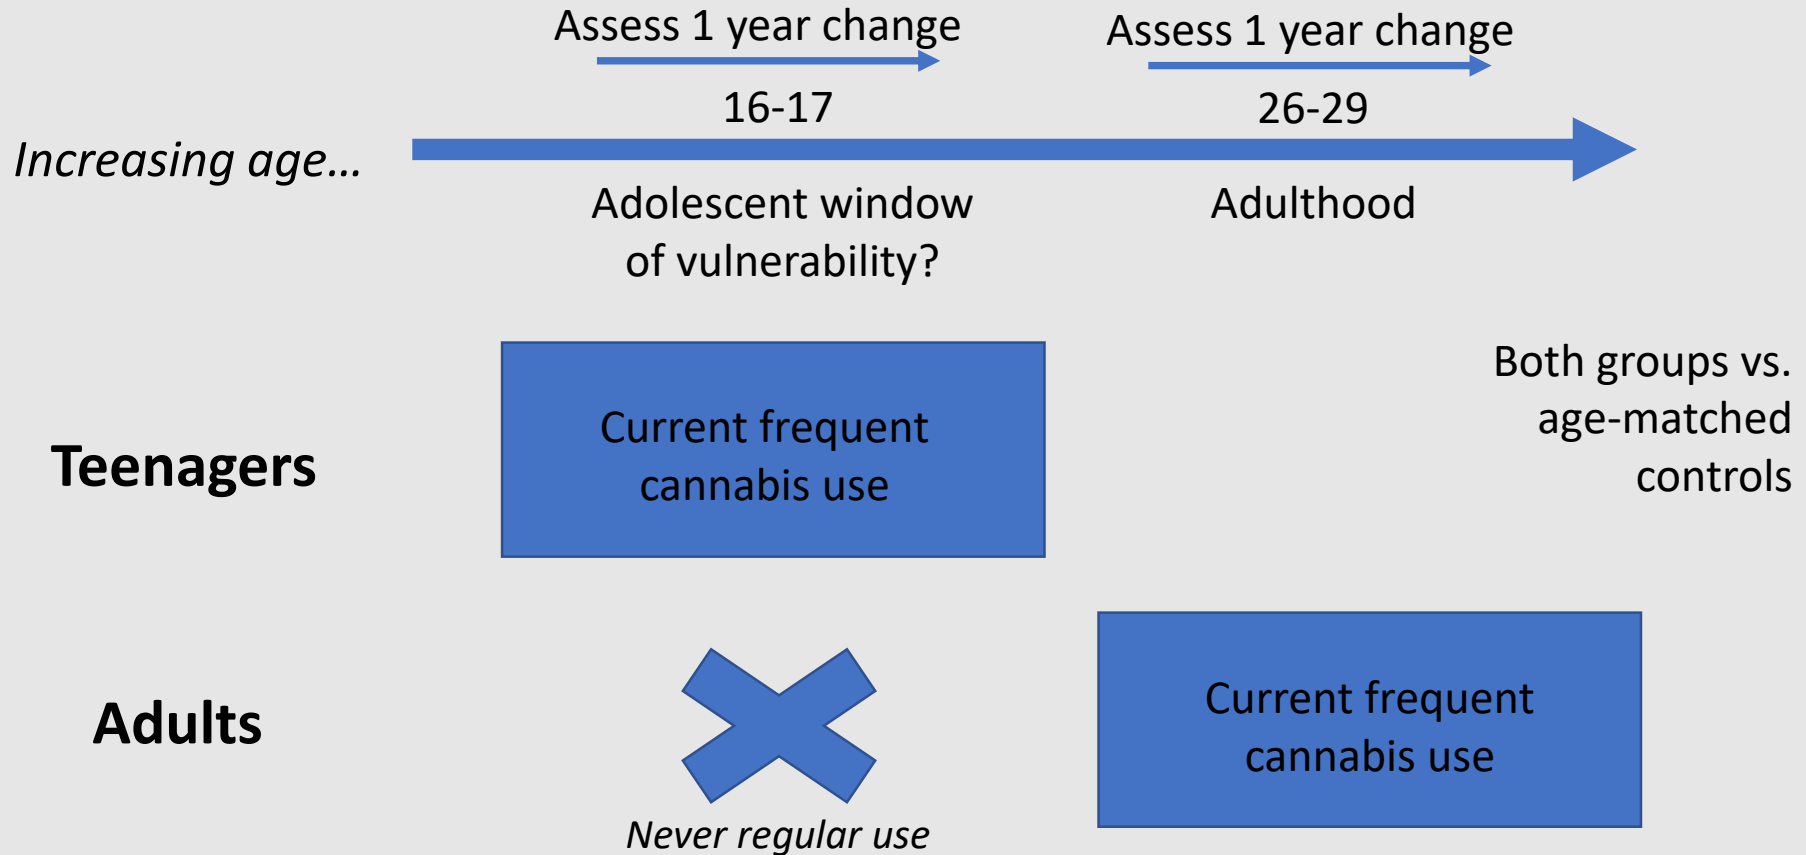

- A subset of above participants.
- n=35 in each group.

Assessments:  $\beta$ =Baseline,  $\lambda$ =Longitudinal, \* =Biological assays, =Brain imaging

	Controls	Users 
<b>Teenagers:</b> 	<ul style="list-style-type: none"><li>• 16-17 years</li><li>• Used cannabis <math>\leq 10</math> days ever.</li><li>• Used tobacco or cannabis <math>\geq 1</math> days.</li><li>• No recent (past month) cannabis use</li></ul>	<ul style="list-style-type: none"><li>• 16-17 years</li><li>• Use cannabis 1-7 days per week</li></ul>
<b>Adults:</b> 	<ul style="list-style-type: none"><li>• 26-29 years</li><li>• Used cannabis <math>\leq 10</math> days ever.</li><li>• Used tobacco or cannabis <math>\geq 1</math> days.</li><li>• No recent (past month) cannabis use</li></ul>	<ul style="list-style-type: none"><li>• 26-29 years</li><li>• Use cannabis 1-7 days per week</li><li>• <u>No weekly use before age 18</u></li></ul>

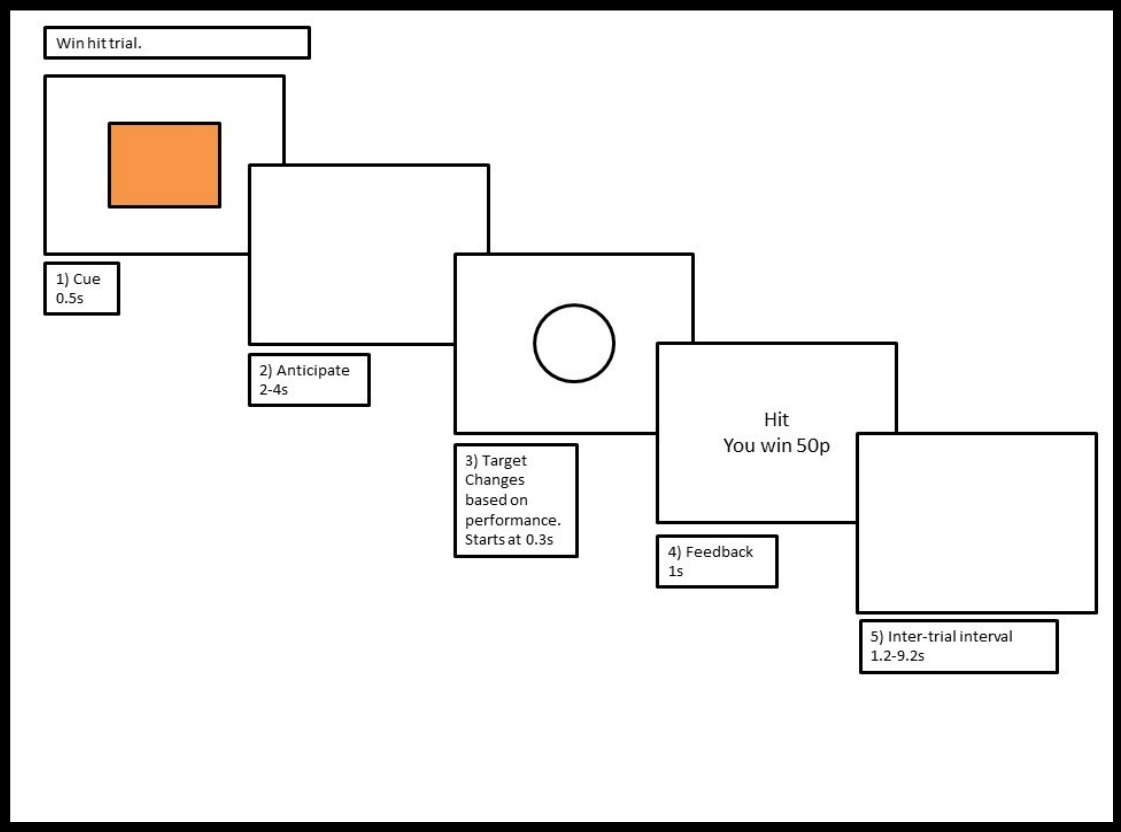

Exclusion criteria for all:

1. Regular use of other illicit drugs.
2. Receiving treatment for mental health condition.
3. History of psychosis.

- ***Current recruitment.*** Very close to completing recruitment for the baseline sample for study 1 (n=255) and study 2 (n=115).
- ***Addiction.*** MINI for DSM-5 CUD (Sheehan et al., 1998) and CUDIT-R (Adamson et al., 2010).
- ***Psychotic-like symptoms.*** (2 week adapted) Psychotomimetic States Inventory (Mason et al., 2008).
- ***Neural correlates of reward processing.*** Monetary incentive delay (MID) task (Knutson et al., 2001)

# Monetary incentive delay task

Key contrasts:

Reward anticipation (vs. no reward)

Reward feedback (vs. no reward)

- Age-group by user-group interactions, such that teenage cannabis users have:
  - stronger addiction to cannabis than adult cannabis users.
  - greater psychotic-like symptoms than adult cannabis users.
  - weaker neural response during reward anticipation and feedback.

(relative to age-matched controls)

- Introduction: adolescence as a period of heightened vulnerability to the harmful effects of cannabis?
- Methods and aims of the CannTeen study
- **Preliminary cross-sectional results**
  - Addiction
  - Psychotic-like symptoms
  - Neural correlates of reward processing
- Discussion

# Participant demographics

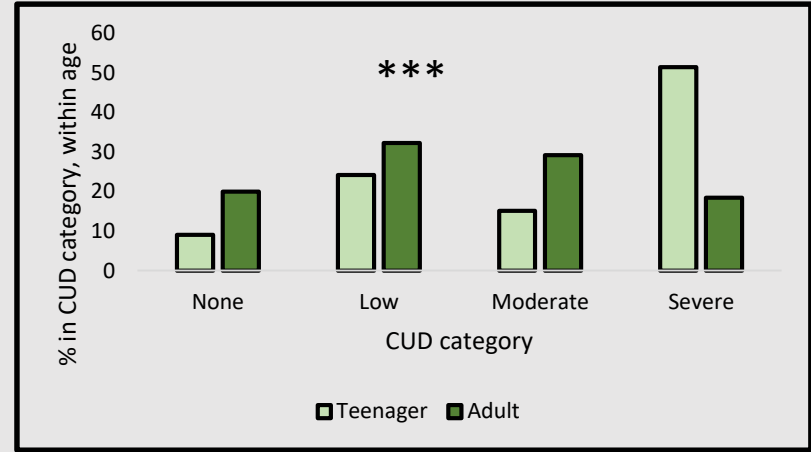

Variable	Teenager		Adult		Difference
	Control	User	Control	User	
Sex (f/m) [total]	34/29 [63]	30/37 [67]	30/30 [60]	31/34 [65]	None
Age (years) (SD)	17.13 (0.47)	17.10 (0.58)	27.36 (1.02)	27.63 (1.19)	Adults > teenagers***
Cannabis frequency (days/week) (SD)	NA	4.44 (1.91)	NA	4.31 (2.02)	None
Cannabis quantity (grams/day on day of use) (SD)	NA	1.13 (0.84)	NA	0.56 (0.63)	Teenagers > adults***
Number of total days of cannabis use (SD)	3.15 (2.89)	NA	4.18 (3.04)	NA	None
AUDIT (SD)	4.51 (3.51)	6.21 (4.52)	5.47 (4.36)	6.35 (4.34)	Users > controls*
Mother's education level (SD)	4.89 (1.90)	4.86 (2.07)	4.07 (2.46)	4.52 (2.14)	Teenagers > Adults*

\* $p < 0.05$ , \*\*\* $p < 0.001$

Cannabis frequency matched between user groups and age matched between age groups

# Addiction within users (DSM)

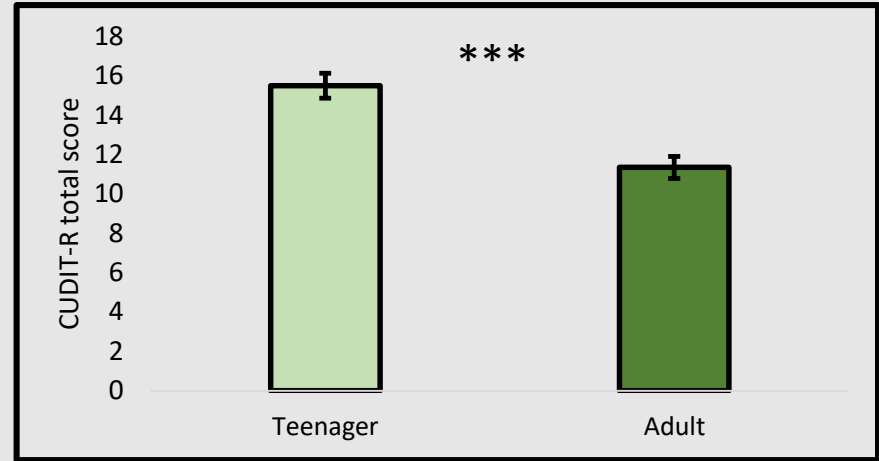

- Teenage n=67, adult n=64
- DSM:  $\chi_3=16.56$ ,  $p<0.001$
- Logistic regression predicting severe CUD

Predictor	Odds ratio (OR)	95% CI OR	p value
Age (teen vs. adult)	3.28	1.26, 8.53	0.015
Cannabis frequency (dpw)	1.41	1.12, 1.77	0.004
Cannabis quantity (grams on a day of use)	1.35	0.75, 2.46	0.319
Sex (male vs. female)	0.80	0.34, 1.90	0.606
Mother's education, SES	0.99	0.80, 1.23	0.940

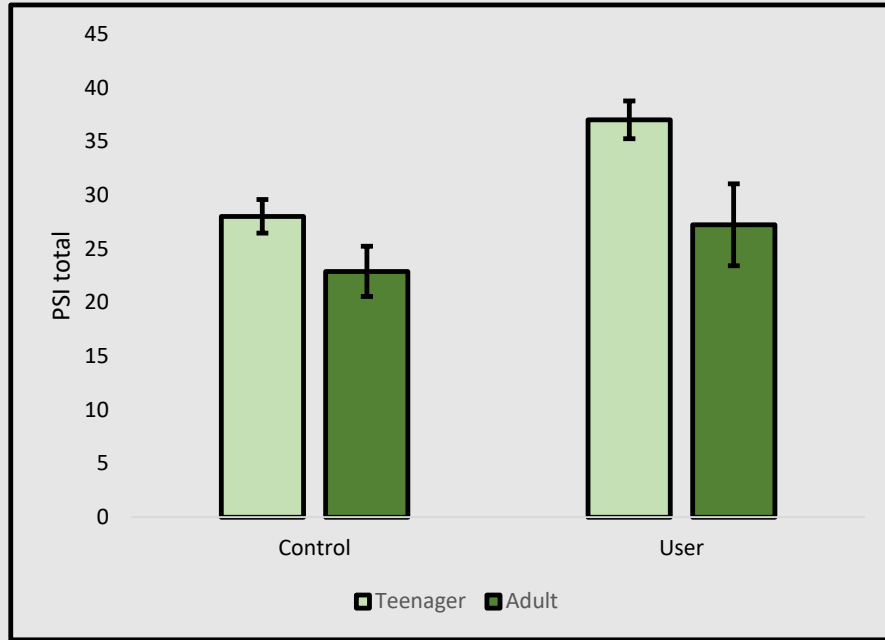

# Addiction with users (CUDIT-R)

- Teenage n=67, adult n=65
- $t_{130}=4.85, p<0.001, d=0.60$
- Linear regression predicting CUDIT-R score

Predictor	Unstandardised beta	SE (b)	p value
<i>Age (teen vs. adult)</i>	<i>3.07</i>	<i>0.86</i>	<i>0.001</i>
<i>Cannabis frequency (dpw)</i>	<i>1.03</i>	<i>0.20</i>	<i>&lt;0.001</i>
<i>Cannabis quantity (grams on a day of use)</i>	<i>1.72</i>	<i>0.57</i>	<i>0.003</i>
Sex (male vs. female)	-1.03	0.79	0.20
Mother's education, SES	-0.248	0.20	0.21

# Psychotic-like symptoms

- Teenagers > adults ( $F_{1,250}=15.157$ ,  $p<0.001$ ,  $\eta_p^2=0.057$ ).
- Users > controls ( $F_{1,250}=12.131$ ,  $p=0.001$ ,  $\eta_p^2=0.046$ )
- No interaction between age-group and user-group.
- Additive, rather than interactive, effect of age-group and user-group.

n	Teenage	Adult
Control	63	60
User	66	65

Supplementary motor area

Anterior cingulate cortex

Insula

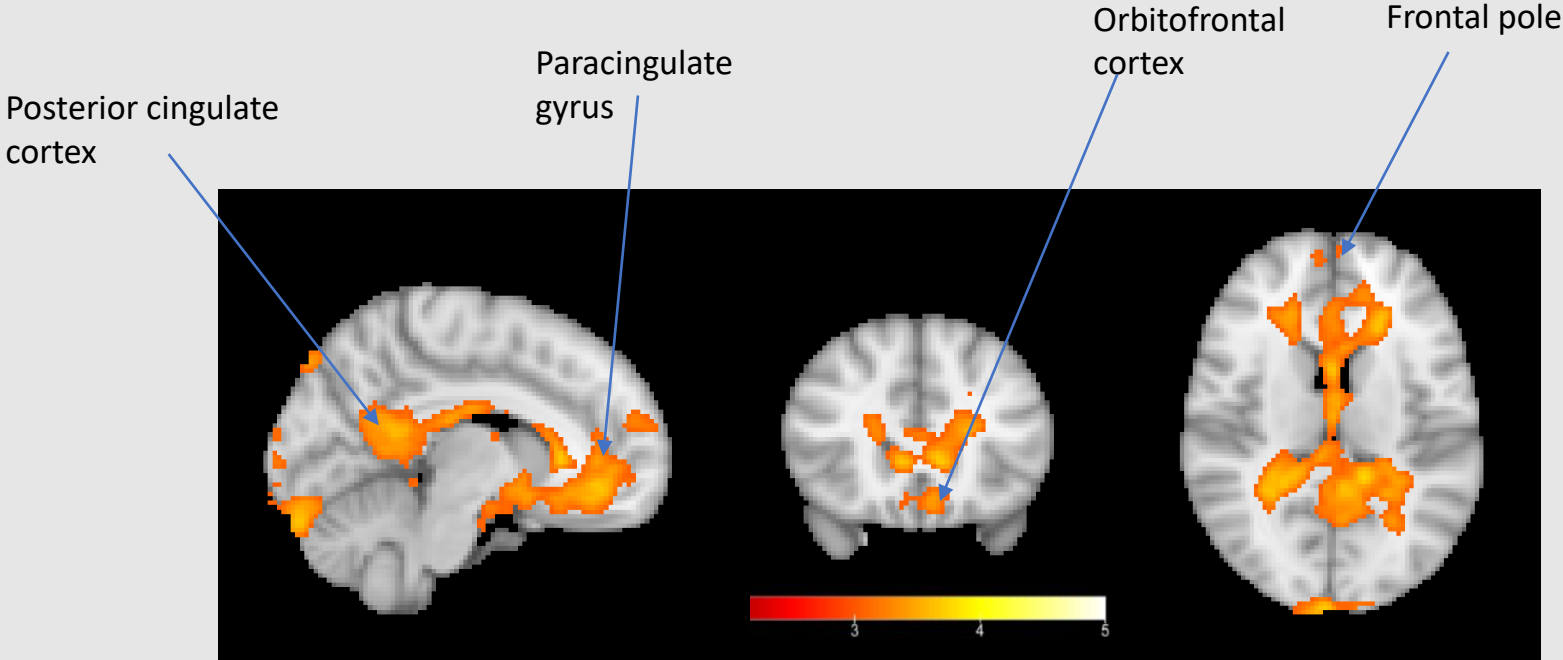

Thalamus

Caudate (dorsal striatum)

Clusterwise corrected,  $z > 2.3, p < 0.05$

n	Teenage	Adult
Control	32	34
User	23	26

# MID – whole brain – feedback – overall task

Bilateral frontal pole

- Introduction: adolescence as a period of vulnerability to the harmful effects of cannabis?
- Methods and aims of the CannTeen study
- Preliminary cross-sectional results
  - Addiction
  - Psychotic-like symptoms
  - Neural correlates of reward processing
- **Discussion**

- Teenage cannabis users are more likely to have cannabis use disorder than adult cannabis users.
- Teenagers (vs. adults) and cannabis users (vs. controls) have more subclinical psychotic-like symptoms. But no differential association between cannabis use and psychotic-like symptoms for teenagers and adults.
- Cannabis users have greater brain activity than controls in the frontal pole when winning money, but no relationship with age and no interaction between age and user-group.

- Window of adolescent vulnerability for developing cannabis use problems.
  - Why teenage vulnerability?
  - Dare to delay?
  - Or different populations?
- Additive effect on subclinical psychotic-like symptoms of being a teenager and a cannabis user.
- Cannabis users neurally hypersensitive to reward feedback.
- Strengths and limitations of existing, cross-sectional data.
- Longitudinal changes to come.
